Art Unit: Unknown

PROVISIONAL PATENT APPLICATION
TRANSMITTAL

Commissioner for Patents
Box PROVISIONAL PATENT APPLICATION
Washington, D.C. 20231

Sir:

Transmitted herewith for filing under 37 C.F.R. § 1.53(c) is the provisional patent
application of:

Francois ANDRE
20, rue du Petit Pont
78180 Montigny-Le-Bretonneux
FRANCE

Marcel DELAFORGE
26, rue Henri Rochefort
91000 Evry
FRANCE

Nicolas LOISEAU
Residence Les Oliviers
5, avenue des Marots
31770 Colomiers
FRANCE

Enclosed are:

- ☒ Specification, Claim(s), and Abstract (761 pages).
- ☒ Informal drawings (7 sheets, Figures 1-5).
- ☒ Application Data Sheet (37 CFR 1.76).

The filing fee is calculated below:

	Rate	Fee Totals
Basic Fee	\$160.00	\$160.00
<input type="checkbox"/> Small Entity Fees Apply (subtract of above):	=	\$0.00
TOTAL FILING FEE:	=	\$160.00

- ☒ A check in the amount of \$160.00 to cover the filing fee is enclosed.
- ☒ Further, Applicant, by and through his attorney of record, hereby expressly abandons the application as of the filing date of this letter. This is an abandonment of the application only, and is not to be construed as an abandonment of the invention disclosed in the application. It is respectfully requested that the Office acknowledge abandonment of the application as of the filing date of this letter in a communication mailed to the undersigned.
- ☒ The Commissioner is hereby authorized to charge any additional fees which may be required regarding this application under 37 C.F.R. §§ 1.16-1.17, or credit any overpayment, to Deposit Account No. 19-0741. Should no proper payment be enclosed herewith, as by a check being in the wrong amount, unsigned, post-dated, otherwise improper or informal or even entirely missing, the Assistant Commissioner is authorized to charge the unpaid amount to Deposit Account No. 19-0741.

Please direct all correspondence to the undersigned attorney or agent at the address indicated below.

Respectfully submitted,

Date Oct. 28, 2002

A method for performing restrained dynamics docking of one or multiple substrates on multi-specific enzymes

5 The present invention relates to a method for performing restrained dynamics docking of one or several substrates having allosteric or synergistic effect on enzymes presenting multispecific and flexible active site. It also concerns a method for determining the 3D-structure of active sites that are flexible and can adapt to different substrates, which is the case for multispecific enzymes such as cytochrome
10 P450.

Background

As of today, various computer graphics systems allow to generate molecular models
15 of large molecules such as proteins from the PDB structural data obtained using X-ray crystallography and NMR. We can cite for example MODELLER, MATCHMAKER (Tripos), or 3D graphical environments for molecular modeling such as SYBYL (Tripos) or INSIGHT II (Accelrys).

20 Substrates as well as inhibitors or agonists often act by binding to particular regions of an enzyme or receptor referred as the active site. In industry, the purpose of using these 3D models is to assess the main features of the molecules which are involved in the binding to the active site. New molecules that fit the active site can be designed.

25 Biological interactions are not possible without flexibility and motion. The molecular dynamics simulations which recreate the successive events in the binding process of a molecule and thermodynamic parameters implicated in such process is therefore of great interest in the design of active molecules.

30 Nevertheless, the methods proposed in the art are based on a relatively low level of calculations of few parameters. It relies only on the molecule energy constrained

with a fixed geometry. It relies only on the interaction energy between the molecule and the active site frozen in a fixed geometry

Consequently, there is a need for a model replicating *in silico* the natural process of molecular interactions.

The method according to the invention provides both minimizations and molecular dynamics calculations. More specifically, it provides a new approach which is more appropriate to flexible structures, hereafter referred as "restrained dynamics docking" or "soft-restrained restrained dynamics docking". This technique employs constrained dynamics simulations, where the only constraints are active site-substrate distances.

For example, to explain and predict drug metabolism in organisms, in which the cytochrome P450 (CYP) superfamily of haem-thiolate enzymes plays a central role, it is of large interest to dispose of a molecular picture of the binding sites responsible for the biotransformation. Efficiency of the prediction is then directly related to the molecular precision of the model, which resolution must be obtained at the atomic level to exploit the model for further docking studies.

20

In mammalian, hepatic cytochrome P450s constitute the major enzymes involved in the metabolism of exogenic compounds. Among them, isozymes of the CYP3 family (such as CYP3A1 and 3A2 in rat, and CYP3A4 in human) are known to metabolize the majority of drugs in clinical use. These are multi-specific enzymes, able to metabolize a large variety of structurally diverse chemicals, generally fairly lipophilic, within a broad range of molecular sizes from testosterone (Mw 288) to cyclosporin A (Mw 1203). Consequently, any molecular model describing correctly the multiple substrate specificity (that takes into account large variations in molecular size and chemical structures), and substrate cooperativity effects within the active site (when two or more drugs interact), is of considerable scientific and industrial interest. Such a molecular model must be able to rationalize the binding of the diverse known substrates, and the orientations of the molecules in the binding

site that account for their known positions of metabolism (such as N-demethylations, benzylic hydroxylations etc.).

As no high-resolution 3D structure of CYP3A is today publicly available, due to continuing difficulties in promoting crystallization of intrinsic membrane proteins or due to an unusual conformational flexibility that would explain how CYP3A4 can accommodate various substrates, it is necessary to rebuild a 3D model structure, integrating the known biochemical data of CYP3A4 and the structural data of other members of the CYP superfamily. X-ray crystallographic determinations of several bacterial P450 enzymes in the 1990s (see table 1 for a summary of structural data) have stimulated numerous attempts in modeling microsomal P450S such as human CYP3A4. The chapter 6 of the book "Guide to Cytochromes P450: structure and function" written by David F.V. Lewis reviews the current status of structural and modeling investigations of the P450 family (Lewis 2001). This review was however written just before the release of the first mammalian P450 structure (2C5), still today the only one mammalian template available.

Table 1

CYP isoform crystallized	PDB code (resol.)	Organism	Function	No of residues	Reference
P450 cam (complexed by CO+camphor)	3cpp (1.9 Å)	<i>Pseudomonas Putida</i>	Camphor Monooxygenase	414	(Poulos et al. 1985) (Raag and Poulos 1989)

P450 BM3	2hpd (2 Å)	<i>Bacillus megaterium</i>	Fatty acid monooxygenase	471	(Ravichandran et al. 1993)
P450 eryF (6-deoxyerythronolide B bond)	1oxa (2.1 Å)	<i>Saccharopolyspora erythraea</i>	Erythromycin biosynthesis 6S-hydroxylation of 6-deoxyerythronolide B	403	(Cupp-Vickery and Poulos 1995)
P450 nor	1rom (2 Å)	<i>Fusarium oxysporum</i> (denitrifying fungus)	Nitric Oxide Reductase	403	(Park et al. 1997)
P450 2C5	1dt6 (3 Å)	(membrane-type Mammalian) Rabbit	Progesterone 21-Hydroxylase	489	(Williams et al. 2000)
P450 CYP119 4-Phenylimidazole	1f4t (1.93 Å)	<i>Sulfobolus Solfataricus</i> Thermophilic bact.	unknown	368	(Yano et al. 2000)

Bond					
P450 CYP51 4-Phenylimidazole Bond	1e9x (2.1 Å)	<i>Mycobacterium Tuberculosis</i>	14 α -sterol demethylase	455	(Podust et al. 2001)

Table 1: the eight X-ray crystal structures of P450s available in 2002: six bacterial, one fungal (P450_{nor}), one mammalian (CYP2C5). The P450_{cam}, P450_{terp}, P450_{eryF}, P450_{nor} belong to class I P450s enzymes, whereas P450_{BM3} belongs to class II enzymes, like microsomal enzymes CYP2C5 and 3A4. P450_{BM3} structure is therefore *a priori* more relevant to rebuilding a structural model of CYP3A4, but since the CYP2C5 X-Ray structure has been released, it became obvious that the structural homology between the other bacterial enzymes and microsomal enzymes was better than expected from the poor homology of primary structure (< 20%).

Then, the relevance of using class I and class II structures together for rebuilding models of class II P450s was no more questionable. The structural model of human CYP3A4 described in the present work was rebuilt using the six first structures listed above, with no preference in the structural alignment. The two last bacterial structural sets CYP51 and CYP119 were not incorporated into the modeling process.

All the proposed models of CYP3A4 obtained by homology modeling are thus so far based on bacterial crystal structure templates: the first was proposed by Ferenczy and Morris and used the X-ray structure of bacterial P450_{cam} as unique template structure (Ferenczy and Morris 1989). Another model was built later by David F.V. Lewis, using also a unique template structure, the P450_{BM3} structure, which was supposed to be more relevant as a template since this P450 was the only one class II enzyme with known three-dimensional structure (Lewis et al. 1996). A third model, based on a multiple structure template, was built by Szklarz and Halpert, using the four first X-ray crystal structures available P450_{cam}, P450_{terp}, P450_{eryF}, and P450_{BM3}. This four-bacterial template approach strategy is closer to our rebuilding strategy, but was still missing some relevance in the absence of a mammalian template. In our hands, the incorporation of the mammalian 2C5 crystal structure into rebuilding steps of models of cytochrome P450 3A4 proved to be decisive. Inclusion of 2C5 crystal structure had indeed a profound effect on the

structural alignment with the five non-mammalian structures, resulting in a different topology of the active site and a marked divergence between the model and each individual template. The advantage of our multiple-template approach resides essentially in the availability of a final template that can be used to rebuild various
5 mammalian cytochromes P450.

More recently, two new bacterial P450 crystal structures emerged in the literature (also listed in table 1): CYP51 (PDB code 1e9x), from *Mycobacterium tuberculosis*, that catalyzes the oxidative removal of 14 α -methyl group from sterol precursors in
10 sterol biosynthesis in yeast and fungi (ergosterol), plants (phytosterol) and mammals (cholesterol), for its potential in the design of antifungal agents (Podust et al. 2001). And CYP119 (PDB code 1f4t), from the thermophilic archaeon *Sulfolobus solfataricus*, the first P450 identified in *Archaea*, for its interest in understanding the enhanced thermal stability of the structure, especially in the
15 region of the active site (Yano et al. 2000). Those two structures have been shown to exhibit the typical bacterial P450 fold, with some exceptions in the topology. They have not been included as structural templates in the modeling steps of the present model. The names of newly discovered P450s follow the now accepted nomenclature of David R. Nelson (Nelson 1999).

20

The protein databank (Brookhaven Protein Databank, <http://www.rcsb.org/pdb/>) currently indicates that there are 76 separate crystal structures available for the eight crystallized P450s, plus 7 crystal structures on hold (Sept 1st, 2002), the majority of which containing either bond substrates or inhibitors. Table 1 provides the relevant
25 information about the structural templates used for human CYP3A4 model rebuilding. The idea behind homology modeling is that proteins belonging to the same functional class and showing a strong sequence similarity, adopt a similar fold (review in (Hilbert et al. 1993)). Known analogous structures are then used to generate a template or parent structure for the unknown protein to be modeled. The
30 reliability of the various methods employed depend mostly on the number of experimental 3D structures that can be aligned. Knowing that for pairs of distantly related proteins (with residue identity of about 20%) the regions having the same fold will represent less than half of each molecule, the regions where the folds differ

will predominate, and the divergence of sequence must be compensated by a higher number of homologous proteins to align (Chothia and Lesk 1986). Below 50% of sequence identity, the deviation in structurally not conserved regions becomes significant, and loop regions are difficult to predict. It is generally accepted that below 20% of sequence identity, the prediction turns out to be hazardous, and fold assignment methods are best replaced by *ab initio* methods, that ideally attempt to predict the native structure only from the primary sequence of the protein to be modeled. But produced models so far had the correct fold for only a few small protein domains (Sanchez et al. 2000).

10

Model rebuilding

The strategy of model rebuilding in the case of the P450 family is strongly driven by the low degree of homology between bacterial and mammalian cytochrome P450s (table 2).

Table 2: Sequence identities between the various crystallized cytochrome P450s and human CYP3A4 (source LALIGN, algorithm of Huang and Miller, published in Adv. Appl. Math. (1991) 12:337-357). For P450 BM3, Swissprot code name

CPXB_BACME, it corresponds to the fusion of P450 and a Reductase, thus is displays twice the number of residues; see <http://www.expasy.org/cgi-bin/niceprot.pl?P14779>

- 5 Our global scheme, which steps are described hereafter, is founded on a combination of methods developed in the literature for different purposes in protein structure determination studies. The principle of the primary steps, until the generation of a correct alignment of P450 primary sequences, is described in (Jean et al. 1997). The last steps are summarized in (Loiseau 2002).

10

Identification of common structural blocks (CSBs) between all selected 3D structures.

- CSBs define the common local folds which set up the vertebral column of the model (results in (Loiseau 2002)). The non conserved regions, that can be parts of
 15 secondary structures or non-structured regions as loops, will be rebuilt with no initial structural information.

Multiple alignment of crystalline P450s, on the basis of CSBs determination: the target sequence of human cytochrome P450 3A is aligned against the multiple
 20 alignment obtained from the CSBs of step 1 (with assessment of accuracy using online tools of multiple alignment such as CLUSTALW 1.8, etc..). This produces the key sequence alignment which allows the generation of the template structure used for the rebuilding of the various CYP3A models.

- 1) Generation of distance and dihedral angles constraints.
- 25 2) Selection of rotamers for side chains in CSBs.
- 3) Calculation of a set of structures using DYANA software. Loops are rebuilt between CSBs.
- 4) Structure optimization under XPLOR software.

30

Description

- Therefore, in a first aspect, the invention relates to a method for designing a 3-dimensional (3-D) model of a protein, the 3-dimensional representation of at least
5 three family members has already been experimentally obtained, [said 3-dimensional representation presenting similarities], comprising the steps of:
- a. identification of common structural blocks (CSB) among said members of said family,
 - b. alignment of the amino-acids primary sequence of said family members
10 according to said structural similarities, represented by said CSBs, in order to obtain a first alignment,
 - c. alignment of said protein as compared on said first alignment, in order to obtain a second alignment, wherein:
 - i. alignment of said protein is performed in order to maximize
15 the amino-acids alignment between said protein and said first alignment,
 - when one or more consensus amino-acid exists in said aligned structural blocs in said first alignment, and in the amino-acid
20 sequence of said protein, said consensus amino-acids are anchors of said second alignment,
 - ii. no insertion or deletion of amino-acids can be performed in the aligned CSBs, wherein insertion or deletions are possible
25 in non-aligned structural blocks, if better to align the primary amino-acids sequences,
 - d. definition of the atomic 3-D structure of structural blocs of said protein, according to the 3-D structure of the blocks of said family members,
 - e. definition of the local constraints (distance and angles) for the atoms that are not
30 structurally determined after step d. (that are not in the conserved structural blocks),
 - f. selection of rotamers,

- g. determination of a family of whole 3-D model structures of said protein, taking into account said atomic 3-D structure of structural blocs obtained in step d., said local constraints defined in step e., and said rotamers defined in step f.,
- h. optimization of said family of 3-D models obtained in step g., by
- 5 i. discarding sequences that present topological defects, and
- ii. recalculating 3-D structures by taking electrostatic forces into account, and performing the method again from step c. downward, with modifications in the alignment between the primary sequence of said protein and said first alignment, when the obtained model structures do not take
- 10 known efficient mutations into account.

In preferred embodiment, said 3-dimentional representation of family members has been obtained by crystallography or NMR.

The alignment of said common structural blocks in steps b. and c. can be performed

15 by use of the GOK software as described in Jean et al., 1997.

In addition, step d. is preferably performed according to the following rules:

- i. at a given position, when residues are identical between all the template structures and the target sequence, the 3D coordinates of the reference
- 20 residues are purely assigned to the target residue,
- ii. When residues differ, only the coordinates of the backbone atoms are assigned ($C\alpha$), and sometimes $C\beta$ when they exist.

In the above depicted method, the definition of local constraints in step e. is

25 performed by analysis of the allowed regions in Ramachandran diagram.

Furthermore, distances and angles are preferably selected in step e. by the following rules:

- i. all distances for which the lower bondary was less than 8 Å.
- 30 ii. all the distances involving at least one side-chain atom, to preserve the spatial arrangement between CSBs

- iii. all the distances involving atoms of any active group such as an heme group, to fix as much as possible the neighborhood of said active group, such as an iron atom

Angular constraints are preferably selected in step e. by the following rule:

- 5 i. dihedral angles ϕ and ψ of all residues located in CSBs are defined as constraints, given by the average values of corresponding ϕ , ψ angles in said family members +/- the standard deviation

10 To practice the method of the invention, rotamers in step f. can be selected from the couples according to the tables of Dunbrack and Karplus and step g. can be performed with the DYANA software, as described in Güntert et al, 1997.

In addition, the optimization in step h. comprises the use of the X-Plor software, as described in A. T. Brunger, X-PLOR, version 3.1. A system for X-ray
15 crystallography and NMR, Yale University Press, New Haven, CT (1992) and A. T. Brunger, Molecular replacement with X-PLOR: PC-refinement and free R value. In: Proceedings of the Daresbury Study Weekend on Molecular Replacement, Daresbury, United Kingdom (1992), 49-61.

20 The method according to the invention is particularly applicable to a cytochrome P450, such as the cytochrome P450 3A4 (SEQ ID N° 1). In this regards, for performing the first alignment can be performed using cytochrome P450 family members are chosen from Nor, (SEQ ID N° 2), Ery F (SEQ ID N° 3), terp (SEQ ID N° 4), Cam (SEQ ID N° 5), BM3 (SEQ ID N° 6) and 2C5 (SEQ ID N° 7).

25

In a second embodiment, the invention is directed to a model 3-D structure of a protein, obtained by the method as described above and more particularly to the cytochrome P450 3A4 model.

30 Regarding the P450 3A4 model, the main residues involved in the recognition of the substrate are C97; R104; F101; F107; F247; F303 and C376.

More specifically, R104 allows allows to capture the substrate that is near of the entry site and to accompany to the active site. F303 is implicated in the

recognition of the substrate in the active site. F107; F247 and F303 are involved in the recognition at the modulation site responsible for positive regulation.

For more details on F103 see : Domanski, T.L., et al., Analysis of four residues within substrate recognition site 4 of human cytochrome P450 3A4: role in
 5 steroid hydroxylase activity and alpha-naphthoflavone stimulation. Arch Biochem Biophys, 1998. 350(2): p. 223-32. (mutants I300, F303, A304, and T308).

10 Features of this model comprise the three dimensional atomic coordinates of Table 3, for C- α , and the (ϕ , ψ) couples of Table 4.

In a third embodiment, the invention contemplates a method for designing a protein, biological functions of which are altered, comprising:

- 15 a) obtaining a 3-D model of said protein by the method of as depicted above,
 b) analyzing said model of step a., and determining the amino-acids that are putatively involved in the biological functions of said protein,
 c) changing said amino-acids by mutating the corresponding nucleotides on the nucleic acid sequence coding for said protein, in order to obtain a mutated
 20 protein having altered properties.

In another embodiment, the invention relates to a computer-assisted method for performing restrained dynamics docking of a substrate on an enzyme, a 3-D structure of which is available, comprising the steps of

- 25 j. determining a force field, and independently simulating the presence of said enzyme in said force field,
 k. minimizing the potential energy (E_p) linked to said force field of said 3-D structure, wherein the spatial position some atoms of said enzyme is fixed, and wherein the other atoms are mobile, by allowing mobility of the mobile atoms,
 30 by
 i. simulating an increase in temperature (in order to give kinetic energy), and
 ii. minimizing the potential energy by re-specifying the temperature as 0 Kelvin (K);

- l. optionally repeating step b in order to obtain other E_p minima, wherein said E_p minima are such that the structure of the protein remains folded,
- m. minimizing E_p in said force field of said 3-D structure, wherein all the atoms of the protein are mobile, by
 - 5 i. simulating an increase in temperature (in order to give kinetic energy), and
 - ii. minimizing the potential energy by re-specifying the temperature as 0 Kelvin (K),
- n. simulating, at 0 K the presence of said substrate next to said enzyme,
- o. optionally generating a dynamic on said substrate and enzyme (simulating an
 - 10 increase in temperature, in order to allow mobility of the atoms),
- p. generating some constraints to said substrate, in order to impose that it has interaction with said enzyme,
- q. generating a dynamic on said substrate and enzyme, with said constraints imposed in step p.,
- 15 r. optionally, generating a dynamic on said substrate and enzyme without said constraints of step p.

In this method for performing restrained dynamics docking, said fixed atoms in step b. are the backbone atoms N-C α -CO in the first minimization step and only

20 C α in subsequent minimization steps.

In addition, kinetic energy is simulated by temperature increase to about 100 K for about 5-20 ns.

The force field in step a. comprises forces linked to

- a. the distance between atoms,
- 25 b. the angles of valence,
- c. the diedric angles,
- d. the deformation with regard to plan,
- e. the electrostatic field,
- f. the Van der Waals forces,
- 30 g. hydrogen bonds.

The constraints in step p. are attraction constraints to force said substrate in the active site, and wherein said constraints are not prejudiced to the exact spatial conformation of the substrate in the active site. These constraints are final

distance constraints between some atoms of said substrate and some atoms of amino-acids present in said active site.

Preferably, step o. is performed with a simulated temperature of between about
 5 15 and 50 K, step q. is performed with a simulated temperature of between about
 15 and 50 K, and step r. is performed with a simulated temperature of between
 about 200 and 350 K.

This method is particularly suited for multispecific protein such as a cytochrome
 10 P450. The cytochrome can be cytochrome P450 3A4, and said structure can be
 the structure obtained by the method of the invention described above, in
 particular the model structure defined with the features of Table 3 and 4.

The substrate can be a small organic compound which size can range for
 15 example from MW 288 (testosterone) to MW 1203 (cyclosporine A).

In a still another embodiment, the invention is aimed at a computer-assisted
 method for performing restrained dynamics docking of at least two substrates on
 an enzyme, a 3-D structure of which is available, consisting of performing the
 20 steps j, k, l, m, n, o, p, q and r depicted above with a first substrate and
 repeating said steps with a second substrate when the first substrate reaches an
 unconstrained molecular dynamic.

The first and second substrates can be the same molecule or different molecules.
 The first and second substrates can display either an allosteric or effect
 25 synergistic effect.

This method can be practiced with substrates that are inhibitors (competitive,
 uncompetitive, non competitive) or display an inhibitor-base mechanism. It can
 also be practice with an agonist and any molecule interfering with the biological
 30 function of the protein.

This method also embraces a successive repeat of the steps j, k, l, m, n, o, p, q and r depicted above with a 3rd, 4th or 5th substrate, some of them being the same or different molecules.

5 In this method for performing restrained dynamics docking, said fixed atoms in step b. are the backbone atoms N-C α -CO in the first minimization step and only C α in subsequent minimization steps.

In addition, kinetic energy is simulated by temperature increase to about 100 K for about 5-20 ns.

10 The force field in step a. comprises forces linked to

- a. the distance between atoms,
- b. the angles of valence,
- c. the diedric angles,
- d. the deformation with regard to plan,
- 15 e. the electrostatic field,
- f. the Van der Waals forces,
- g. hydrogen bonds.

The constraints in step p. are attraction constraints to force said substrate in the active site, and wherein said constraints are not prejudiced to the exact spatial
20 conformation of the substrate in the active site. These constraints are final distance constraints between some atoms of said substrate and some atoms of amino-acids present in said active site.

Preferably, step o. is performed with a simulated temperature of between about
25 15 and 50 K, step q. is performed with a simulated temperature of between about 15 and 50 K, and step r. is performed with a simulated temperature of between about 200 and 350 K.

This method is particularly suited for multispecific protein such as a cytochrome
30 P450. The cytochrome can be cytochrome P450 3A4, and said structure can be the structure obtained by the method of the invention described above, in particular the model structure defined with the features of Table 3 and 4.
